

# Exceptional Control Flow Wrapup

- **No new examples in these slides**

- I have examples from this past [Monday](#) and [Wednesday](#) that I still need to work through, so I'm planning on spending time doing that.
- I also want to give you some high-level sense as to how the OS supports multiprocessing so that each process can operate as if it owns all of its 4GB (or 256TB, in a 64-bit world) virtual address space.
- I have enough material to carry us through at least the end of Monday's lecture.

- **Reminders**

- Assignment 2 due on Wednesday night. Hard deadline (consuming late days) is two calendar days later.
- Assignment 3, also out on Wednesday, will be an opportunity to leverage **fork**, **waitpid**, **execvp**, signals, and signal handlers to build a fairly sophisticated shell that's more robust and feature-rich than the **simplesh** shell we wrote in lecture.
